1 Proofs of Theorems and Lemmas

1.1 Proof of Theorem 1

Proof By summing out the unobserved latent vector \mathbf{N} , the complete-data likelihood given in (3) of the main manuscript reduces to

$$\sum_{\mathbf{N}} L(\beta, \xi | \mathbf{D}) = \prod_{i=1}^n (\theta_i f(y_i | \xi))^{\delta_i} \exp \{-\theta_i (1 - S(y_i | \xi))\}.$$

Notice that if $\delta_i = 0$, $(\theta_i f(y_i | \xi))^{\delta_i} \exp \{-\theta_i (1 - S(y_i | \xi))\} = \exp \{-\theta_i (1 - S(y_i | \xi))\} \leq 1$. On the other hand, when $\delta_i = 1$, we will show that there exists a constant M such that

$$(\theta_i f(y_i | \xi))^{\delta_i} \exp \{-\theta_i (1 - S(y_i | \xi))\} \leq g_i(\xi) M, \quad (1)$$

where $g_i(\xi) = 1/(1 + \xi \log y_i)_+^{\frac{1}{\xi} + 1}$. The left side of (1) can be rewritten as

$$\begin{aligned} & \frac{f(y_i | \xi)}{1 - S(y_i | \xi)} \cdot (\theta_i (1 - S(y_i | \xi)) \exp \{-\theta_i (1 - S(y_i | \xi))\}) \\ &= \frac{1}{y_i (1 + \xi \log y_i)_+^{\frac{1}{\xi} + 1}} (\theta_i (1 - S(y_i | \xi)) \exp \{-\theta_i (1 - S(y_i | \xi))\}). \end{aligned} \quad (2)$$

Let $g(z) = ze^{-z}$, for $z > 0$, then it can be shown that (see [Chen et al. \[1999\]](#)) there exists a constant $g_0 > 0$ such that

$$g(z) \leq g_0, \forall z > 0. \quad (3)$$

Using (3), we see that (2) is less than or equal to $y_i^{-1} g_0 g_i(\xi)$. Thus taking $M = g_0 \max_{i: \delta_i=1} \{y_i^{-1}\}$, we obtain (1).

Since \mathbf{X}^* is of full rank, there must exist k linearly independent row vectors $\mathbf{x}'_{i_1}, \mathbf{x}'_{i_2}, \dots, \mathbf{x}'_{i_k}$ such that $\delta_{i_1} = \delta_{i_2} = \dots = \delta_{i_k} = 1$. To prove that the posterior given in (4) of the main manuscript is proper, we only need to show that

$$\int_a^b \int_{\mathbb{R}^k} \sum_N L(\beta, \xi | D) \pi(\xi) d\beta d\xi < \infty. \quad (4)$$

Note that the expression in (4) can be written as

$$\begin{aligned} \frac{1}{(b-a)} \int_a^b \int_{\mathbb{R}^k} \sum_N L(\beta, \xi | D) d\beta d\xi &= \frac{1}{(b-a)} \int_a^b \int_{\mathbb{R}^k} \prod_{i=1}^n (\theta_i f(y_i | \gamma))^{\delta_i} \exp\{-\theta_i(1 - S(y_i | \gamma))\} d\beta d\xi \\ &\leq \frac{1}{(b-a)} \int_a^b \int_{\mathbb{R}^k} \left(\prod_{i:\delta_i=0} 1 \right) \\ &\quad \left\{ \prod_{j=1}^k f(y_{i_j} | \xi) \theta_{i_j} \exp\{-\theta_{i_j}(1 - S(y_{i_j} | \gamma))\} \right\} \\ &\quad \left\{ \prod_{i:\delta_i=1, i \neq i_j, j=1, \dots, k} g_i(\xi) M \right\} d\beta d\xi \\ &= \frac{1}{(b-a)} \int_a^b \int_{\mathbb{R}^k} M^{d-k} \left[\prod_{i:\delta_i=1, i \neq i_j, j=1, \dots, k} g_i(\xi) \right] \\ &\quad \prod_{j=1}^k f(y_{i_j} | \xi) \theta_{i_j} \exp\{-\theta_{i_j}(1 - S(y_{i_j} | \gamma))\} d\beta d\xi, \end{aligned} \quad (5)$$

where $\theta_{i_j} = \exp(\mathbf{x}'_{i_j} \beta)$ and \mathbb{R}^k denotes the k -dimensional Euclidean space. Now we make the transformation $u_j = x'_{i_j} \beta$ for $j = 1, 2, \dots, k$. This is a one-to-one linear transformation from β to $\mathbf{u} = (u_1, \dots, u_k)'$. Thus (5) is proportional to

$$\begin{aligned} &\int_a^b \int_{\mathbb{R}^k} \left[\prod_{i:\delta_i=1, i \neq i_j, j=1, \dots, k} g_i(\xi) \right] \prod_{j=1}^k f(y_{i_j} | \xi) \exp\{u_j - (1 - S(y_{i_j} | \xi)) \exp(u_j)\} d\mathbf{u} d\xi \\ &= \int_a^b \left[\prod_{i:\delta_i=1, i \neq i_j, j=1, \dots, k} g_i(\xi) \right] \left\{ \prod_{j=1}^k f(y_{i_j} | \xi) \int_R \exp\{u_j - (1 - S(y_{i_j} | \xi)) \exp(u_j)\} du_j \right\} d\xi \\ &= \int_a^b \left[\prod_{i:\delta_i=1, i \neq i_j, j=1, \dots, k} g_i(\xi) \right] \prod_{j=1}^k \frac{f(y_{i_j} | \xi)}{1 - S(y_{i_j} | \xi)} d\xi. \end{aligned} \quad (6)$$

The last equality holds, since $\int_R \exp\{u_j - (1 - S(y_{i_j} | \xi)) \exp(u_j)\} du_j = 1/(1 - S(y_{i_j} | \xi))$. Notice that

$$\frac{f(y_{i_j} | \xi)}{1 - S(y_{i_j} | \xi)} = \frac{1}{y_{i_j} (1 + \xi \log y_{i_j})_+^{\frac{1}{\xi} + 1}} \leq M_1 \cdot g_{i_j}(\xi),$$

where $M_1 = \max_{i:\delta_i=1} y_i^{-1}$. Ignoring the constant, (6) is less than or equal to $\int_a^b \prod_{i:\delta_i=1} g_i(\xi) d\xi$.

Thus we only need to prove that $g(\xi) := \prod_{i:\delta_i=1} g_i(\xi)$ is bounded in $[a, b]$. We show that for every i with $\delta_i = 1$, $g_i(\xi)$ is bounded in $[a, b]$. Recall that (5) from the main manuscript is in force. We consider two cases of this condition separately.

- If $\exp(-1/b) < y_i < \exp(-1/a)$, $-1/\log y_i$ is either less than a or greater than b , $a < 0 < b$. So $\min_{\xi \in [a, b]} (1 + \xi \log y_i)_+^{1/\xi+1}$ is bounded away from zero. Hence $g_i(\xi)$ is bounded in $[a, b]$.
- On the other hand, if $y_i \geq \max(\exp(-1/a), e)$, then $1 + \xi \log y_i \rightarrow 0$ when $\xi \rightarrow -1/\log y_i$. But

$$\lim_{\xi \rightarrow -\frac{1}{\log y_i}} g_i(\xi) = 0^{\log y_i - 1} = \begin{cases} 1 & \text{if } y_i = e \\ 0 & \text{o.w.} \end{cases}.$$

Hence $g_i(\xi)$ is bounded on $[a, b]$.

So $g(\xi) = \prod_{i:\delta_i=1} g_i(\xi)$ is bounded in $[a, b]$, thus we have $\int_a^b g(\xi) d\xi < \infty$.

1.2 Proof of Theorem 3

Proof By summing out the unobserved latent vector \mathbf{N} , the complete-data likelihood given in (3) of the main manuscript reduces to

$$\sum_{\mathbf{N}} L(\beta, \xi | \mathbf{D}) = \prod_{i=1}^n (\theta_i f(y_i | \xi))^{\delta_i} \exp \{-\theta_i (1 - S(y_i | \xi))\}.$$

If $\delta_i = 0$, $(\theta_i f(y_i | \xi))^{\delta_i} \exp \{-\theta_i (1 - S(y_i | \xi))\} = \exp \{-\theta_i (1 - S(y_i | \xi))\} \leq 1$. When $\delta_i = 1$, we will show that there exists a constant M such that

$$(\theta_i f(y_i | \xi))^{\delta_i} \exp \{-\theta_i (1 - S(y_i | \xi))\} \leq h_i(\xi) M, \quad (7)$$

where $h_i(\xi) = 1/(1 + \xi \log y_i)_+$. The left side of (7) can be rewritten as

$$\begin{aligned} & \frac{f(y_i | \xi)}{1 - S(y_i | \xi)} \cdot (\theta_i (1 - S(y_i | \xi)) \exp \{-\theta_i (1 - S(y_i | \xi))\}) \\ &= \frac{\frac{1}{y_i} (1 + \xi \log y_i)_+^{\frac{1}{\xi}-1} \exp[-(1 + \xi \log y_i)_+^{\frac{1}{\xi}}]}{1 - \exp[-(1 + \xi \log y_i)_+^{\frac{1}{\xi}}]} (\theta_i (1 - S(y_i | \xi)) \exp \{-\theta_i (1 - S(y_i | \xi))\}) \end{aligned} \quad (8)$$

Let $\kappa_1(z) = ze^{-z}$, and $\kappa_2(z) = \frac{ze^{-z}}{1-e^{-z}}$ for $z > 0$. It can be shown that there exists a constant $h_0 > 0$ such that

$$\kappa_i(z) \leq h_0, \forall z > 0 \quad i = 1, 2. \quad (9)$$

Using (9), (8) is less than or equal to $y_i^{-1} h_0^2 h_i(\xi)$. Thus taking $M = h_0^2 \max_{i:\delta_i=1} \{y_i^{-1}\}$, we obtain (7).

Doing similar calculations as in the proof of Theorem 1, we see that the posterior density in (4) of the main manuscript is proper since $h_i(\xi)$ is bounded in $[a, b]$ for all i with $\delta_i = 1$.

1.3 Proof of Lemma 1

Proof The cumulative distribution function of T is

$$F(t|\alpha, \lambda) = 1 - \exp \left\{ - \left(\frac{t}{\lambda} \right)^\alpha \right\}. \quad (10)$$

Thus we have $P(\log T \leq y) = P(T \leq \exp(y)) = 1 - \exp\{-\frac{\exp(\alpha y)}{\lambda^\alpha}\}$. Assuming $\mu = \log \lambda, \sigma = \frac{1}{\alpha}$, we have $P(\log T \leq y) = 1 - \exp\{-\frac{\exp(\alpha y)}{\lambda^\alpha}\} = 1 - \exp(-\exp(\frac{y-\mu}{\sigma}))$. Thus, $\log T \sim \text{mGEV}(\mu = \log(\lambda), \sigma = \frac{1}{\alpha}, \xi = 0)$.

2 Real Data Application for the MGEV model: Melanoma Cancer Data

We consider a melanoma cancer data set from the National Cancer Institute SEER database (SEER*Stat(2013) [www.seer.cancer.gov]). The data consists of observations on 1152 subjects who were diagnosed with melanoma cancer in the county of North Bergen of the state of New Jersey between 2000 and 2007 and had been undergoing treatment since diagnosis. All the cases were followed annually and vital status is recorded. All the subjects were diagnosed with only melanoma cancer and were followed up since diagnosis until the end of December, 2007. Subjects who died due to melanoma cancer were considered failed and the rest (those who died due to other causes, dropped, or survived until the end of the study) were considered censored. By the end of 2007, 152 patients had died of melanoma cancer (13.2%) while the remaining were censored. The variable considered in this analysis is: lifetime in months since diagnosis. Subjects with survival time 0 were removed from the data set. The covariates included are: age, gender, stage of the disease (local, other including regional or distant) and marital status (married or divorced/separated/widowed/single). Table 1 lists some basic information for the data set.

We fit both MGEV and Weibull models to the data for better comparisons. We assume the similar prior distributions on μ , σ and ξ as described in the case study of the main manuscript. We assume normal prior for β with mean 0 and variance σ_β^2 . For the hyper parameters, we take $a = 0.5$, $a_\sigma = 0.01$, $b_\sigma = 2$, $\sigma_\beta^2 = 36$ and $\sigma_\mu^2 = 16$. Gibbs sampler with Metropolis-Hastings steps is used as before to get the posterior samples for parameters. For this data set, we have 60,000 MCMC iterations. Convergence was checked using the trace plots, ergodic mean plots and also the autocorrelation plots for all the parameters. We find that 10,000 iterations are adequate as a burn-in.

We fit a Weibull(λ, α) model with covariates as in the previous case. Again for simplicity, we assume that λ , α and β are independent. We assume normal priors for all the β as before. Also, we take $\alpha \sim \text{Gamma}(a_\alpha, b_\alpha)$ and $\lambda^2 \sim \text{IG}(a_\lambda, b_\lambda)$ with $a_\lambda = 0.1$, $b_\lambda = 2$, $a_\alpha = 0.01$, $b_\alpha = 0.01$ and $\sigma_\beta^2 = 49$.

We plot the difference of logarithm of CPO at each data point of the two models fitted (MGEV and Weibull) as before. We also compute LPML and DIC values for each model fit for comparison.

2.1 Results

Figure 1(a) shows the estimated Kaplan-Meier curve along with the estimated survival functions of both the MGEV and the Weibull models. The survival curves are drawn for data without considering the covariates just to provide an initial idea about the appropriateness of the chosen model. It appears that the MGEV and the Weibull model both fit the data adequately. We now consider Bayesian analysis with the covariates included. Tables 2 and 3 show the posterior estimates for all the parameters.

Table 2 shows the estimates of the β 's from both the fitted models match in sign and with the exception of the intercept, they are also close in values. Figure 1(b) shows the CPO plot of the difference. 65% of the points lie above zero (blue dots) giving us an indication that MGEV model is better suited to the data in hand. Table 4 shows the LPML and DIC values of the two model fits. We find that our proposed model MGEV has significantly lower DIC and higher LPML in comparison to Weibull fit.
